1 Introduction

normal distributions are the best, lets transform everything to normal

2 Background

2.1 Change of Variable for Probability Density Function

Let X have a continuous density f_X . Let $g : \mathbb{R} \rightarrow \mathbb{R}$ be piece-wise strictly monotone and continuously differentiable, i.e. there exists intervals I_1, I_2, \dots, I_n which partition \mathbb{R} such that g is strictly monotone and continuously differentiable on the interior of each I_i . For each i , $g : I_i \rightarrow \mathbb{R}$ is invertible on $g(I_i)$ and let g_i^{-1} be the inverse function. Let $Y = g(X)$ and $\Lambda = \{y | y = g(x), x \in \mathbb{R}\}$ be the range g . Then the density function f_Y of Y exists and is given by

$$f_Y(y) = \sum_{i=1}^n f_X(g_i^{-1}(y)) \left| \frac{\partial g_i^{-1}(y)}{\partial y} \right| \mathbf{1}_{\Lambda}(y) \quad (1)$$

This is also true for more than one dimension where the absolute value of the derivative becomes the determinant of the Jacobian.

2.2 Laplace Approximation

The Laplace approximation (LPA) is a tool to fit a normal distribution to the PDF of a given other distribution. The only constraints for the other distribution are: one peak (mode/ point of maximum) and twice differentiable. Laplace proposed a simple 2-term Taylor expansion on the log pdf. If $\hat{\theta}$ denotes the mode of a pdf $h(\theta)$, then it is also the mode of the log-pdf $q(\theta) = \log h(\theta)$. The 2-term Taylor expansion of $q(\theta)$ therefore is:

$$q(\theta) \approx q(\hat{\theta}) + q'(\hat{\theta})(\theta - \hat{\theta}) + \frac{1}{2}(\theta - \hat{\theta})q''(\hat{\theta})(\theta - \hat{\theta}) \quad (2)$$

$$= q(\hat{\theta}) + 0 + \frac{1}{2}(\theta - \hat{\theta})q''(\hat{\theta})(\theta - \hat{\theta}) \quad [\text{since } q'(\hat{\theta}) = 0] \quad (3)$$

$$= c - \frac{(\theta - \mu)^2}{2\sigma^2} \quad (4)$$

where c is a constant, $\mu = \hat{\theta}$ and $\sigma^2 = \{-q''(\hat{\theta})\}^{-1}$. The right hand side of the last line matches the log-pdf of a normal distribution $N(\mu, \sigma^2)$. Therefore the pdf $h(\theta)$ is approximated by the pdf of the normal distribution $N(\mu, \sigma^2)$ where $\mu = \hat{\theta}$ and $\sigma^2 = \{-q''(\hat{\theta})\}^{-1}$. Note, that even though this derivation is done for the one dimensional case only, it is also true for the multidimensional case. The second derivative just becomes the Hessian of the pdf at the mode.

2.3 Exponential Family

A pdf that can be written in the form

$$p(x|w) = h(x) \cdot \exp(\phi(x)^\top w - \log Z(w)), \quad \text{where} \quad Z(w) := \int_{\mathbf{X}} \exp(\phi(x)^\top w) dh(x)$$

is called an exponential family where $\phi(x) : \mathbb{X} \rightarrow \mathbb{R}^d$ is called sufficient statistics, $w \in \mathbb{R}^d$: natural parameters, $\log Z(w) : \mathbb{R}^d \rightarrow \mathbb{R}$: (log) partition function (normalization constant), and $h(x) : \mathbb{X} \rightarrow \mathbb{R}_+$: base measure.

2.4 Chi2 <-> Normal

It is well-known that a Chi-squared distribution with k degrees of freedom describes the sum squares of k independent, standard normal random variables. To introduce a certain ‘trick’ we show the forward and backward transformation between Chi-squared and normal distribution by assuming $k = 1$.

Let X be normal with $\mu = 0, \sigma^2 = 1$. Let $Y = X^2$ and therefore $g(x) = x^2$, which is neither monotone nor injective. Take $I_1 = (-\infty, 0)$ and $I_2 = [0, +\infty)$. Then g is monotone and injective on I_1 and I_2 and $I_1 \cup I_2 = \mathbb{R}$. $g(I_1) = (0, \infty)$ and $g(I_2) = [0, \infty)$. Then $g_1^{-1} : [0, \infty) \rightarrow \mathbb{R}$ by $g_1^{-1}(y) = -\sqrt{y}$ and $g_2^{-1} : [0, \infty) \rightarrow \mathbb{R}$ by $g_2^{-1}(y) = \sqrt{y}$. Then

$$\left| \frac{\partial g_i^{-1}(y)}{\partial y} \right| = \left| \frac{1}{2\sqrt{y}} \right| = \frac{1}{2\sqrt{y}}$$

Applying Equation 1 we can transform a normal distribution to a chi-squared.

$$f_Y(y) = f_X(g_1^{-1}(y)) \left| \frac{\partial g_1^{-1}(y)}{\partial y} \right| \mathbf{1}_{\wedge}(y) + f_X(g_2^{-1}(y)) \left| \frac{\partial g_2^{-1}(y)}{\partial y} \right| \mathbf{1}_{\wedge}(y) \quad (5a)$$

$$= \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y}{2}\right) \frac{1}{2\sqrt{y}} + \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y}{2}\right) \frac{1}{2\sqrt{y}} \quad (y > 0) \quad (5b)$$

$$= \frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{y}} \exp\left(-\frac{y}{2}\right) \quad (5c)$$

$$= \frac{1}{2^{\frac{1}{2}} \Gamma(\frac{1}{2})} y^{-\frac{1}{2}} \exp\left(-\frac{1}{2}\right) \quad (5d)$$

$$= \chi^2(1) \quad (5e)$$

The ‘trick’ was to split up the variable transformation in two parts to adjust for the fact that the space of the chi-squared and the Normal are different. We can reverse the same procedure to get from a chi-squared to a normal distribution. We keep the variable names from before. Let $X = \sqrt{Y}$ and therefore $h(x) = \sqrt{x}$. Then $h_1^{-1} : \mathbb{R} \rightarrow (-\infty, 0)$ by $h_1^{-1}(x) = -x^2$ and $h_2^{-1} : \mathbb{R} \rightarrow [0, \infty)$ by $h_2^{-1}(x) = x^2$. Then

$$\left| \frac{\partial h_i^{-1}(y)}{\partial y} \right| = |2y|$$

and

$$f_X(x) = f_Y(h_1^{-1}(x)) \left| \frac{\partial h_1^{-1}(y)}{\partial y} \right| \mathbf{1}_{\wedge}(y) + f_Y(h_2^{-1}(x)) \left| \frac{\partial h_2^{-1}(y)}{\partial y} \right| \mathbf{1}_{\wedge}(y) \\ = \frac{1}{\sqrt{2\pi}} \frac{1}{2\sqrt{x^2}} \exp\left(-\frac{x^2}{2}\right) |2x| \mathbf{1}_{(-\infty, 0)}(x) + \frac{1}{\sqrt{2\pi}} \frac{1}{2\sqrt{x^2}} \exp\left(-\frac{x^2}{2}\right) |2x| \mathbf{1}_{[0, \infty)}(x) \quad (6a)$$

$$= \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right) \quad (6b)$$

$$= \mathcal{N}(x; \mu = 0, \sigma^2 = 1) \quad (6c)$$

which is defined on the entirety of \mathbb{R} .

2.4.1 A generalization to matrices

“In general, an $n \times n$ matrix with n distinct nonzero eigenvalues has 2^n square roots. Such a matrix, A , has a decomposition VDV^{-1} where V is the matrix whose columns are eigenvectors of A and D is the diagonal matrix whose diagonal elements are the corresponding n eigenvalues λ_i . Thus the square roots of A are given by $VD^{\frac{1}{2}}V^{-1}$, where $D^{\frac{1}{2}}$ is any square root matrix of D , which, for distinct eigenvalues, must be diagonal with diagonal elements equal to square roots of the diagonal elements of D ; since there are two possible choices for a square root of each diagonal element of D , there are 2^n choices for the matrix $D^{\frac{1}{2}}$ ” - *Wikipedia*.

The Chi-squared distribution can be seen as the 1D special case of the matrix transformation and therefore has $2^1 = 2$ possible options for $\lambda^{\frac{1}{2}}$, namely $-\lambda^{\frac{1}{2}}$ and $+\lambda^{\frac{1}{2}}$. Higher dimensional functions such as Wishart and inverse Wishart have 2^n different possibilities which have to be accounted for within the transformation.

An alternative way to see the variable transform

Another way to interpret the transformation from Chi2 to normal and back is by introducing the sign function. Say we have a variable X which is distributed according to a Gaussian with $\mu = 0, \sigma = 1$ as in the above setting. We introduce the following transformation $g(a, b)$:

$$\begin{aligned} A &= \text{sign}(X) \\ B &= |X| \\ W &= \text{sign}(X) \\ Z &= \sqrt{|X|} \cdot |W| \end{aligned}$$

with the inverse $g^{-1}(w, z)$.

The determinant of the Jacobian of this transformation is as follows

$$\begin{aligned} \det(J) &= \left| \begin{bmatrix} \frac{\partial w}{\partial a} & \frac{\partial w}{\partial b} \\ \frac{\partial z}{\partial a} & \frac{\partial z}{\partial b} \end{bmatrix} \right| \\ &= \left| \begin{bmatrix} 1 & 0 \\ 0 & \frac{|w|}{2\sqrt{z}} \end{bmatrix} \right| \\ &= \frac{|w|}{2\sqrt{z}} \end{aligned}$$

The joint distribution of w and z can now be seen as

$$\begin{aligned} f_{w,z}(w, z) &= f_{a,b}(g^{-1}(w, z)) \det(J) \\ &= f_a(w) f_b(w, z) \frac{|w|}{2\sqrt{z}} \\ &= f_a(w) \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{|w|^2 z}{2}\right) \frac{|w|}{2\sqrt{z}} \end{aligned}$$

Since we know that W can only take the values -1 and 1 we can easily integrate over W .

$$\begin{aligned}
f_z &= \int dw f_{w,z} \\
&= \int dw f_a(w) \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{|w|^2 z}{2}\right) \frac{|w|}{2\sqrt{z}} \\
&= 1 \cdot \int dw \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{|w|^2 z}{2}\right) \frac{|w|}{2\sqrt{z}} \\
&= \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{|-1|^2 z}{2}\right) \frac{|-1|}{2\sqrt{z}} + \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{|1|^2 z}{2}\right) \frac{|1|}{2\sqrt{z}} \\
&= \frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{z}} \exp\left(-\frac{z}{2}\right) \quad z > 0
\end{aligned}$$

Similarly we can construct a transformation for the inverse transformation, i.e. from Chi2 to Gaussian. Assume we have a variable X which is distributed according to a Chi2 distribution. Our transform is

$$\begin{aligned}
A &= \text{sign}(X) \\
B &= X \\
W &= \text{sign}(X) \\
Z &= X^2 \cdot \sqrt{W}
\end{aligned}$$

Then we get a determinant of the Jacobian

$$\begin{aligned}
\det(J) &= \left| \begin{bmatrix} \frac{\partial w}{\partial a} & \frac{\partial w}{\partial b} \\ \frac{\partial z}{\partial a} & \frac{\partial z}{\partial b} \end{bmatrix} \right| \\
&= \left| \begin{bmatrix} 1 & 0 \\ 0 & 2z\sqrt{w} \end{bmatrix} \right| \\
&= 2z\sqrt{w}
\end{aligned}$$

And the joint distribution becomes

$$\begin{aligned}
f_{w,z} &= f_{a,b}(g^{-z}(w, z)) \det(J) \\
&= f_a(w) f_b(w, z) 2z\sqrt{w} \\
&= f_a(w) \frac{1}{z^2 w} \exp\left(-\frac{z^2 w}{2}\right) 2z\sqrt{w}
\end{aligned}$$

We can marginalize over W as follows. Note that X is distributed according to a Chi2 and therefore only allows positive values. W is therefore only 1.

TODO: this kinda feels like cheating AND has to be refined. No variables should be assigned twice.

3 Laplace Propagation

If we have a distribution $p(x)$ in the ‘standard base’ x , i.e. as we usually use it, we can transform this distribution to another basis y via the change of variable for PDF formula. The resulting distribution is $p_y(x(y))$ where $x(y)$ is the inverse transform of denoted as $g^{-1}(x)$.

We define Laplace Propagation as the procedure of finding a different base y for $p(x)$ in which $p_y(x(y))$ is as close to a Gaussian as possible. In this base a Laplace approximation is performed

to yield a Gaussian $q(y)$. The mean μ for q is computed by setting the first derivative $\frac{\partial p_y(x(y))}{\partial y}$ to 0 and solving for y . The covariance matrix Σ is computed by inverting the Hessian $H = \frac{\partial^2 p(x(y))}{\partial^2 y}$, multiplying it with -1 and inserting the mode μ . Lastly, a ‘Bridge’ is created that transforms the parameters θ of $p(x(y))$ to the parameters μ, Σ of $q(x(y))$.

TODO: the part above should stand out in some way. Maybe we should put a fancy box around it

While there are no restrictions for the choice of the basis transform (e.g. could be done by a Neural Network), in this paper we choose transforms that fulfill the following desiderata as much as possible: a) the new space of the distribution is \mathbb{R} (or the d -dimensional equivalent) since this implies that the resulting Gaussian from the Laplace approximation is well-defined. b) The sufficient statistics in the new basis are either x in the first entry or x^2 in the second entry since the sufficient statistics of the Gaussian are (x, x^2) and it is therefore likely closer to the Normal distribution. c) The base measure $h(x)$ is 1 since this implies that there are no restrictions on the parameters θ of the distribution in the new base. In the standard basis the Beta distribution’s parameters α, β have to be larger than 1 to yield a uni-modal distribution. Multi-modal distributions yield bad or no valid Laplace approximations and we would therefore prefer $h(x) = 1$. d) Lastly, all ‘Bridges’ should be available in closed-form because it often implies fast computation.

4 General overview

5 Exponential Distribution

5.1 Standard Exponential Distribution

The PDF of the exponential distribution is

$$p(x|\lambda) = \lambda \exp(-\lambda x) \quad (7a)$$

$$= \exp[-\lambda x + \log \lambda] \quad (7b)$$

with $h(x) = 1$, $\phi(x) = x$, $w = -\lambda$ and $Z(\lambda) = -\log \lambda$

5.1.1 Laplace Approximation of the Exponential Distribution

$$\text{log-pdf: } (\log \lambda - \lambda x)$$

$$\text{1st derivative: } -\lambda$$

$$\text{2nd derivative: } 0$$

The Laplace Approximation is not defined since the second derivative is not positive.

Table 3: Distances. MMD and KL div are normed to 1 in the standard basis for better comparison.

Distribution	Basis	Small θ		Medium θ		Large θ	
		MMD ↓	KL ↓	MMD ↓	KL ↓	MMD ↓	KL ↓

5.2 Log-transformed Exponential Distribution

We choose $X = \log(Y)$ and therefore $g(x) = \log(x)$, and $x(y) = g^{-1}(y) = \exp(y)$. Also, $\left| \frac{\partial x(y)}{\partial y} \right| = \exp(y)$. It follows that the new pdf is

$$\mathcal{E}_{Y \log}(y; \lambda) = \lambda \exp(-\lambda x(y)) \cdot \exp(y) \quad (8a)$$

$$= \lambda \exp(-\lambda \exp(y) + y) \quad (8b)$$

$$= \exp[-\lambda \exp(y) + y + \log \lambda] \quad (8c)$$

with $h(y) = 1$, $\phi(x) = (y, \exp(y))$, $w = (1, -\lambda)$ and $Z(\lambda) = \log \lambda$

5.2.1 Laplace Approximation of the log-transformed Exponential Distribution

$$\text{log-pdf: } -\lambda \exp(y) + y + \log \lambda$$

$$\text{1st derivative: } \lambda - \exp(y) + 1$$

$$\text{mode: } y = \log(1/\lambda)$$

$$\text{2nd derivative: } -\lambda \exp(y)$$

$$\text{insert mode: } -\lambda \exp(1/\lambda) = -1$$

$$\text{invert \& times -1: } \sigma^2 = 1$$

Therefore the Laplace approximation in the transformed basis is given by $\mathcal{N}(y, \log(1/\lambda), 1)$.

5.2.2 The Bridge for the log-transformed Exponential Distribution

We have already found μ and σ . The inverse transformation is easily found through the mode $\mu = \log(1/\lambda) \Leftrightarrow \lambda = 1/\exp(\mu)$. In summary:

$$\mu = \log(1/\lambda) \quad (9a)$$

$$\sigma = 1 \quad (9b)$$

$$\lambda = 1/\exp(\mu) \quad (9c)$$

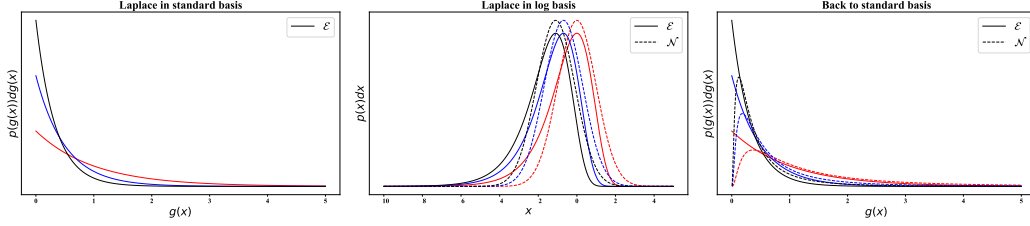

Figure 1: log-Bridge for the Exponential distribution

5.3 Sqrt-transformed Exponential Distribution

We choose $X = \sqrt{Y}$ and therefore $g(x) = \sqrt{x}$, and $x(y) = g^{-1}(y) = y^2$. Also, $\left| \frac{\partial x(y)}{\partial y} \right| = 2y$. It follows that the new pdf is

$$\mathcal{E}_{Y_{sqrt}}(y; \lambda) = \lambda \exp(-\lambda y^2) \cdot 2y \quad (10a)$$

$$= 2 \cdot \exp[\log(y) - \lambda y^2 + \log \lambda] \quad (10b)$$

with $h(y) = 2$, $\phi(y) = (\log(y), y^2)$, $w = (1, -\lambda)$ and $Z(\lambda) = \log \lambda$

5.3.1 Laplace Approximation of the sqrt-transformed Exponential Distribution

$$\text{log-pdf: } \log(2y) - \lambda y^2 + \log \lambda$$

$$\text{1st derivative: } \frac{1}{y} - 2\lambda y$$

$$\text{mode: } y = \sqrt{\frac{1}{2\lambda}}$$

$$\text{2nd derivative: } -\frac{1}{y^2} - 2\lambda$$

$$\text{insert mode: } -\frac{1}{\frac{1}{2\lambda}} - 2\lambda = -4\lambda$$

$$\text{invert \& times -1: } \sigma^2 = \frac{1}{4\lambda}$$

5.3.2 The Bridge for the sqrt-transformed Exponential Distribution

$$\mu = \sqrt{\frac{1}{2\lambda}} \quad (11a)$$

$$\sigma^2 = \frac{1}{4\lambda} \quad (11b)$$

$$\lambda = \frac{1}{2\mu^2} \quad (11c)$$

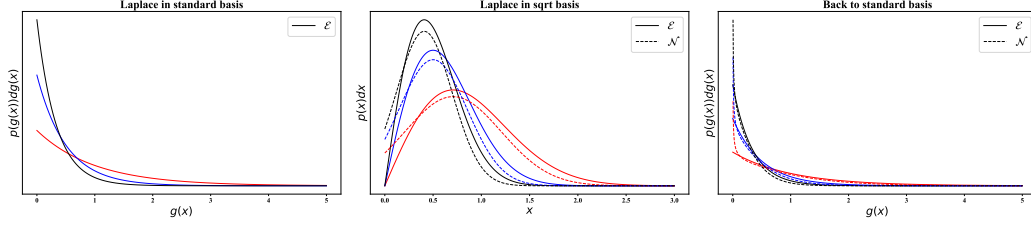

Figure 2: sqrt-Bridge for the Exponential distribution

6 Gamma Distribution

6.1 Standard Gamma Distribution

$$\mathcal{G}_X(x, \alpha, \lambda) = \frac{\lambda^\alpha}{\Gamma(\alpha)} \cdot x^{(\alpha-1)} \cdot e^{(-\lambda x)} \quad (12)$$

where $\Gamma(\alpha)$ is the Gamma function. This can be written as

$$\mathcal{G}_X(x, \alpha, \lambda) = \exp [(\alpha - 1) \log(x) - \lambda x + \alpha \log(\lambda) - \log(\Gamma(\alpha))] \quad (13a)$$

$$= \frac{1}{x} \exp [\alpha \log(x) - \lambda x + \alpha \log(\lambda) - \log(\Gamma(\alpha))] \quad (13b)$$

with $h(x) = \frac{1}{x}$, $\phi(x) = (\log x, x)$, $w = (\alpha, -\lambda)$ and $Z(\alpha, \lambda) = \log(\Gamma(\alpha)) - \alpha \log(\lambda)$.

6.1.1 Laplace Approximation of the Gamma Distribution

To get the LPA of the Gamma function in the standard basis we need its mode and the second derivative of the log-pdf. The mode is already known to be $\hat{\theta} = \frac{\alpha-1}{\lambda}$. For the second derivative of the log-pdf we take the log-pdf and derive it twice and insert the mode for x :

$$\begin{aligned} \text{log-pdf: } & \log \left(\frac{\lambda^\alpha}{\Gamma(\alpha)} \cdot x^{(\alpha-1)} \cdot e^{(-\lambda x)} \right) \\ &= \alpha \cdot \log(\lambda) - \log(\Gamma(\alpha)) + (\alpha - 1) \log(x) - \lambda x \\ \text{1st derivative: } & \frac{(\alpha - 1)}{x} - \lambda \\ \text{mode: } & \frac{(\alpha - 1)}{x} - \lambda = 0 \Leftrightarrow x = \frac{\alpha - 1}{\lambda} \\ \text{2nd derivative: } & -\frac{(\alpha - 1)}{x^2} \\ \text{insert mode: } & -\frac{(\alpha - 1)}{\left(\frac{\alpha-1}{\lambda}\right)^2} = -\frac{\lambda^2}{\alpha - 1} \\ \text{invert and times -1: } & \sigma^2 = \frac{\alpha - 1}{\lambda^2} \end{aligned}$$

The LPA of the Gamma distribution is therefore approximately distributed according to the pdf of $\mathcal{N}(x; \frac{\alpha-1}{\lambda}, \frac{\alpha-1}{\lambda^2})$.

6.2 Log-Transform of the Gamma Distribution

We transform the Gamma Distribution with the Log-Transformation, i.e. $Y = \log(X)$, $g(x) = \log(x)$, $x(y) = g^{-1}(x) = \exp(x)$. Also, $\left| \frac{\partial x(y)}{\partial y} \right| = \exp(y)$. The transformed pdf is

$$\mathcal{G}_{Y_{\log}}(y, \alpha, \lambda) = \frac{\lambda^\alpha}{\Gamma(\alpha)} \cdot x(y)^{(\alpha-1)} \cdot e^{(-\lambda x(y))} \cdot \exp(y) \quad (14a)$$

$$= \frac{\lambda^\alpha}{\Gamma(\alpha)} \cdot \exp(y)^\alpha \cdot e^{(-\lambda \exp(y))} \quad (14b)$$

$$= \exp[\alpha y - \lambda \exp(y) - \Gamma(\alpha) + \alpha \log(\lambda)] \quad (14c)$$

with exponential family parameters $h(y) = 1$, $\phi(y) = (y, \exp(y))$, $\eta = (\alpha, -\lambda)$ and $Z(\alpha, \lambda) = \log(\Gamma(\alpha)) - \alpha \log(\lambda)$.

6.2.1 Laplace Approximation of the log-transformed Gamma Distribution

To get the LPA of the Gamma distribution in the transformed basis we need to calculate its mode and the second derivative of the log-pdf. To get the mode we take the first derivative and set it to zero.

$$\text{log-pdf: } = \alpha \log(\lambda) - \log(\Gamma(\alpha)) + \alpha y - \lambda \exp(y)$$

$$\text{1st derivative: } \alpha - \lambda \exp(y)$$

$$\text{mode: } \alpha - \lambda \exp(y) = 0 \Leftrightarrow y = \log\left(\frac{\alpha}{\lambda}\right)$$

$$\text{2nd derivative: } -\lambda \exp(y)$$

$$\text{insert mode: } -\lambda \exp(\log\left(\frac{\alpha}{\lambda}\right)) = -\alpha$$

$$\text{invert and times -1: } \sigma^2 = \frac{1}{\alpha}$$

The resulting Guassina is $N(y; \log\left(\frac{\alpha}{\lambda}\right), \frac{1}{\alpha})$.

6.2.2 The bridge for the log-transformation

We already know how to get μ and σ from λ and α . To invert we calculate $\mu = \log(\alpha/\lambda) \Leftrightarrow \lambda = \alpha / \exp(\mu)$ and insert $\alpha = \sigma^2$. In summary we have

$$\mu = \log\left(\frac{\alpha}{\lambda}\right) \quad (15a)$$

$$\sigma^2 = \frac{1}{\alpha} \quad (15b)$$

$$\lambda = \frac{1}{\exp(\mu)\sigma^2} \quad (15c)$$

$$\alpha = \frac{1}{\sigma^2} \quad (15d)$$

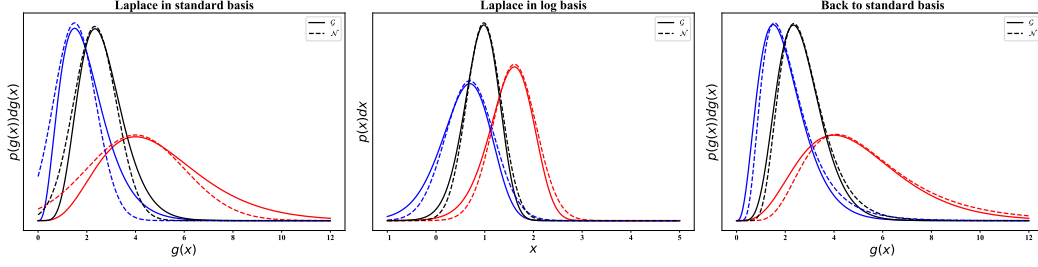

Figure 3: log-Bridge for Gamma distribution

6.3 Sqrt-Transform of the Gamma Distribution

6.3.1 Sqrt-Transformation

We transform the Gamma Distribution with the sqrt-transformation, i.e. $Y = \sqrt{X}$, $g(x) = \sqrt{x}$, $x_1(y) = g_1^{-1}(y) = -y^2$, $x_2(y) = g_2^{-1}(y) = y^2$ and $\left| \frac{\partial x_i(y)}{\partial y} \right| = \left| \frac{\partial g_i^{-1}(y)}{\partial y} \right| = |2y|$. We use the same ‘trick’ as in Subsection 2.4 to split up the transformation in two parts.

$$\mathcal{G}_Y(y) = \frac{1}{2} \cdot \mathcal{G}_X(x_1(y)) \left| \frac{\partial x_1(y)}{\partial y} \right| \mathbf{1}_{\wedge}(y) + \frac{1}{2} \cdot \mathcal{G}_X(x_2(y)) \left| \frac{\partial x_2(y)}{\partial y} \right| \mathbf{1}_{\vee}(y) \quad (16a)$$

$$= \frac{1}{2y^2} \exp[\alpha \log(y^2) - \lambda y^2 - A(\alpha, \lambda)] |2y| \mathbf{1}_{(-\infty, 0)}(y) + \frac{1}{2y^2} \exp[\alpha \log(y^2) - \lambda y^2 - A(\alpha, \lambda)] |2y| \mathbf{1}_{[0, \infty)}(y) \quad (16b)$$

$$= \frac{1}{\sqrt{y}} \exp[2\alpha \log(y) - \lambda y^2 - A(\alpha, \lambda)] \mathbf{1}_{(-\infty, +\infty)}(y) \quad (16c)$$

$$= \frac{1}{\sqrt{y}} \exp[2\alpha \log(y) - \lambda y^2 - A(\alpha, \lambda)] \quad (16d)$$

which is defined on the entirety of \mathbb{R} and is an exponential family with $h(y) = \frac{1}{\sqrt{y}}$, $\phi(y) = (\log(y), y^2)$, $w = (2\alpha, -\lambda)$ and $Z(\alpha, \lambda) = \log(\Gamma(\alpha)) - \alpha \log(\lambda)$.

6.3.2 Laplace Approximation of the sqrt-transformed Gamma Distribution

To get the LPA of the Gamma distribution in the transformed basis we need to calculate its mode and the second derivative of the log-pdf. To get the mode we take the first derivative and set it to zero.

$$\text{log-pdf: } (2\alpha - 1) \log(y) - \lambda y^2 + \alpha \log(\lambda) - \log(\Gamma(\alpha))$$

$$\text{1st derivative: } \frac{2\alpha - 1}{y} - 2\lambda y$$

$$\text{mode: } \frac{2\alpha - 1}{y} - 2\lambda y = 0 \Leftrightarrow y = \sqrt{\frac{\alpha - 0.5}{\lambda}}$$

$$\text{2nd derivative: } -\frac{2\alpha - 1}{y^2} - 2\lambda$$

$$\text{insert mode: } -\frac{2\alpha - 1}{\frac{\alpha - 0.5}{\lambda}} - 2\lambda = -4\lambda$$

$$\text{invert and times -1: } \sigma^2 = \frac{1}{4\lambda}$$

Therefore the LPA now is $\mathcal{N}\left(\sqrt{\frac{\alpha - 0.5}{\lambda}}, \frac{1}{4\lambda}\right)$.

6.3.3 The bridge for the sqrt-transformation

We already know how to get μ and σ from λ and α . To invert we calculate $\mu = \sqrt{\frac{\alpha-0.5}{\lambda}} \Leftrightarrow \alpha = \frac{\mu^2}{\lambda} - 0.5$ and insert $\lambda = \frac{4}{\sigma^2}$. In summary we have

$$\mu = \sqrt{\frac{\alpha - 0.5}{\lambda}} \quad (17a)$$

$$\sigma^2 = \frac{1}{4\lambda} \quad (17b)$$

$$\lambda = \frac{4}{\sigma^2} \quad (17c)$$

$$\alpha = \frac{4\mu^2}{\sigma^2} + 0.5 \quad (17d)$$

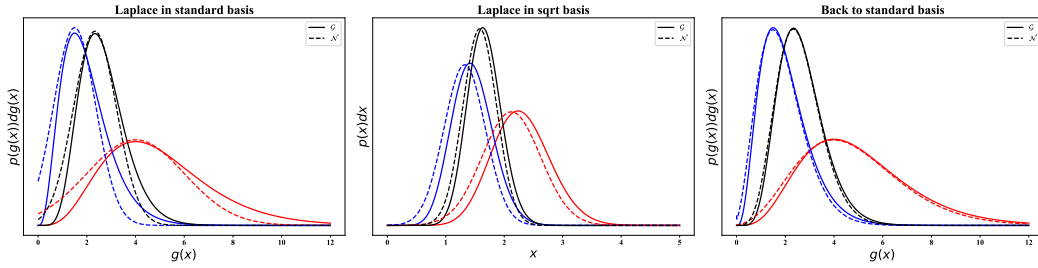

Figure 4: sqrt-Bridge Gamma

7 Inverse Gamma Distribution

7.1 Standard Inverse Gamma Distribution

The pdf of the inverse gamma is

$$\mathcal{IG}(x, \alpha, \lambda) = \frac{\lambda^\alpha}{\Gamma(\alpha)} x^{-\alpha-1} \exp(-\frac{\lambda}{x}) \quad (18a)$$

$$= \exp \frac{1}{x} [-\alpha \log(x) - \lambda/x + \alpha \log(\lambda) - \log \Gamma(\alpha)] \quad (18b)$$

where $h(x) = \frac{1}{x}$, $\phi(x) = (\log(x), x)$, $w = (-\alpha, -\lambda)$ and $Z(\alpha, \lambda) = \log \Gamma(\alpha) - \alpha \log \lambda$.

7.1.1 Laplace Approximation of the standard inverse gamma distribution

$$\text{log-pdf: } (-\alpha - 1) \log(x) - \lambda/x + \alpha \log(\lambda) - \log \Gamma(\alpha)$$

$$\text{1st derivative: } \frac{-\alpha - 1}{x} + \frac{\lambda}{x^2}$$

$$\text{mode: } \frac{-\alpha - 1}{x} + \frac{\lambda}{x^2} = 0 \Leftrightarrow x = \frac{\lambda}{\alpha + 1}$$

$$\text{2nd derivative: } \frac{\alpha + 1}{x^2} - 2\frac{\lambda}{x^3}$$

$$\text{insert mode: } \frac{\alpha + 1}{\frac{\lambda}{\alpha+1}^2} - 2\frac{\lambda}{\frac{\lambda}{\alpha+1}^3} = -\frac{(\alpha + 1)^3}{\lambda^2}$$

$$\text{invert and times -1: } \sigma^2 = \frac{\lambda^2}{(\alpha + 1)^3}$$

with $q(x) = \mathcal{N}(x; \mu = \frac{\lambda}{a+1}, \sigma^2 = \frac{\lambda^2}{(\alpha+1)^3})$.

7.2 Log-Transform of the inverse Gamma distribution

We transform the Inverse Gamma distribution with the log-transformation, i.e. $Y = \log(X)$. Therefore $g(x) = \log(x)$, and thereby $x(y) = g^{-1}(x) = \exp(y)$. It follows that the new pdf is

$$f_{Y_{\log}}(y, \alpha, \lambda) = \frac{\lambda^\alpha}{\Gamma(\alpha)} \exp(y)^{-\alpha-1} \exp(-\lambda/\exp(y)) \cdot \exp(y) \quad (19a)$$

$$= \frac{\lambda^\alpha}{\Gamma(\alpha)} \exp(y)^{-\alpha} \exp(-\lambda/\exp(y)) \quad (19b)$$

$$= \exp \left[-\alpha y - \frac{\lambda}{\exp(y)} - \log \Gamma(\alpha) + \alpha \log(\lambda) \right] \quad (19c)$$

with $h(y) = 1$, $\phi(y) = (y, \exp(y))$, $w = (-\alpha, \lambda)$ and $Z(\alpha, \lambda) = \log \Gamma(\alpha) - \alpha \log \lambda$.

7.2.1 Laplace Approximation of the log-transformed Inverse Gamma Distribution

$$\text{log-pdf: } -\alpha y - \frac{\lambda}{\exp(y)} + C$$

$$\text{1st derivative: } -\alpha + \frac{\lambda}{\exp(y)}$$

$$\text{mode: } -\alpha + \frac{\lambda}{\exp(y)} = 0 \Leftrightarrow y = \log(\lambda/\alpha)$$

$$\text{2nd derivative: } -\frac{\lambda}{\exp(y)^2}$$

$$\text{insert mode: } -\frac{\lambda}{\exp(\log(\lambda/\alpha))^2} = -\alpha$$

$$\text{invert and times -1: } \sigma^2 = \frac{1}{\alpha}$$

7.2.2 The Bridge for the log-transformed Inverse Gamma Distribution

$$\mu = \log \left(\frac{\lambda}{\alpha} \right) \quad (20a)$$

$$\sigma^2 = \frac{1}{\alpha} \quad (20b)$$

$$\alpha = \frac{1}{\sigma^2} \quad (20c)$$

$$\lambda = \frac{\exp(\mu)}{\sigma^2} \quad (20d)$$

7.3 Sqrt-Transform of the inverse Gamma distribution

We transform the Inverse Gamma distribution with the sqrt-transformation, i.e. $Y = \sqrt{X}$. Therefore $g(x) = \sqrt{x}$, and thereby $x(y) = g^{-1}(x) = y^2$. It follows that the new pdf is

$$f_{Y_{\log}}(y, \alpha, \lambda) = \frac{\lambda^\alpha}{\Gamma(\alpha)} y^{2(-\alpha-1)} \exp(-\lambda/y^2) \cdot 2y \quad (21a)$$

$$= \frac{\lambda^\alpha}{\Gamma(\alpha)} y^{-2\alpha-\frac{1}{2}} \exp(-\lambda/y^2) \quad (21b)$$

$$= \frac{1}{\sqrt{y}} \exp \left[-2\alpha \log(y) - \frac{\lambda}{y^2} - \log \Gamma(\alpha) + \alpha \log(\lambda) \right] \quad (21c)$$

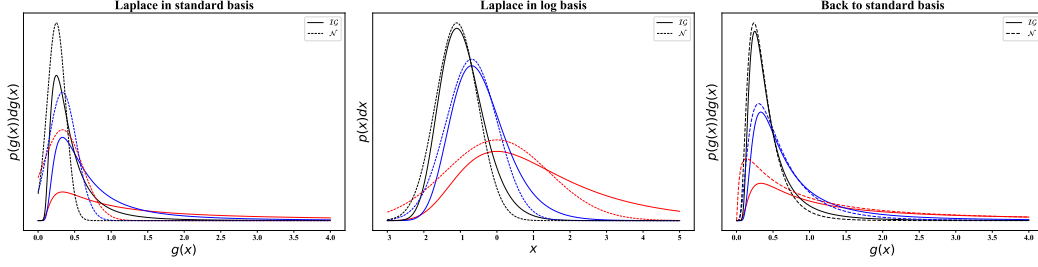

Figure 5: inverse gamma log-bridge

with $h(y) = \frac{1}{\sqrt{y}}$, $\phi(y) = (\log(y), y^2)$, $w = (-2\alpha, -\lambda)$ and $Z(\alpha, \lambda) = \log \Gamma(\alpha) - \alpha \log \lambda$.

7.3.1 Laplace Approximation of the sqrt-transformed Inverse Gamma Distribution

$$\begin{aligned} \text{log-pdf: } & (-2\alpha - 1) \log(y) - \frac{\lambda}{y^2} + C \\ \text{1st derivative: } & -\frac{2\alpha + 1}{y} + 2\frac{\lambda}{y^3} \\ \text{mode: } & y = \sqrt{\frac{\alpha + 0.5}{\lambda}} \\ \text{2nd derivative: } & \frac{2\alpha + 1}{y^2} - 6\frac{\lambda}{y^4} \\ \text{insert mode: } & -4\frac{(\alpha + 0.5)^2}{\lambda} \\ \text{invert and times -1: } & \sigma^2 = \frac{\lambda}{4(\alpha + 0.5)^2} \end{aligned}$$

yielding $q(y) = \mathcal{N}(y; \mu = \sqrt{\frac{\alpha + 0.5}{\lambda}}, \sigma^2 = \frac{\lambda}{4(\alpha + 0.5)^2})$.

7.3.2 The Bridge for the sqrt-transformed Inverse Gamma Distribution

$$\mu = \sqrt{\frac{\lambda}{\alpha}} \quad (22a)$$

$$\sigma^2 = \frac{\lambda}{4\alpha^2} \quad (22b)$$

$$\alpha = \frac{\mu^2}{4\sigma^2} - 0.5 \quad (22c)$$

$$\lambda = \frac{\mu^4}{4\sigma^2} \quad (22d)$$

8 Chi-square Distribution

8.1 Standard Chi-squared distribution

The pdf of the Chi-squared distribution in the standard basis is

$$\chi_X^2(x, k) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2-1} \exp(-x/2) \quad (23a)$$

$$= \frac{1}{x} \exp \left[(k/2) \log(x) - x/2 - \log(2^{k/2} \Gamma(k/2)) \right] \quad (23b)$$

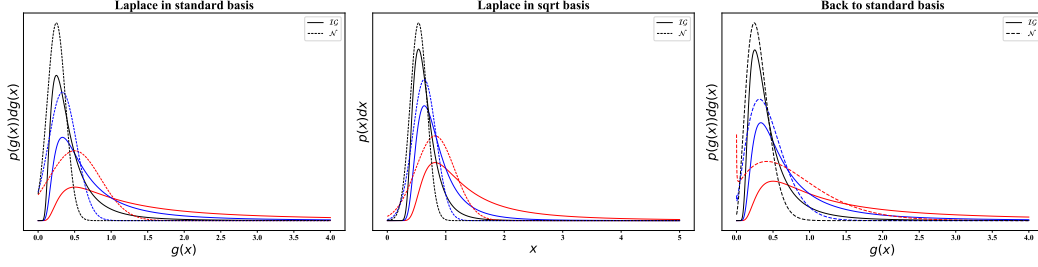

Figure 6: inverse gamma sqrt-bridge

with $h(x) = \frac{1}{x}$, $\phi(x) = (\log(x), x)$, $w = k/2$ and $Z(k) = \log(2^{k/2}\Gamma(k/2))$.

8.1.1 Laplace approximation of the standard Chi-squared distribution

$$\text{log-pdf: } (k/2 - 1) \log(x) - x/2 - \log(2^{k/2}\Gamma(k/2))$$

$$\text{1st derivative: } \frac{k/2 - 1}{x} - \frac{1}{2}$$

$$\text{mode: } \frac{k/2 - 1}{x} - \frac{1}{2} = 0 \Leftrightarrow x = k - 2$$

$$\text{2nd derivative: } -\frac{k/2 - 1}{x^2}$$

$$\text{insert mode: } -\frac{k/2 - 1}{(k - 2)^2} = -\frac{(k - 2)}{2(k - 2)^2}$$

$$\text{invert and times -1: } \sigma^2 = 2(k - 2)$$

8.2 Log-Transformed Chi-squared distribution

we transform the distribution with $g(x) = \log(x)$, i.e. $x(y) = g^{-1}(x) = \exp(y)$. The new pdf becomes

$$\chi_{Y_{\log}}^2(y, k) = \frac{1}{2^{k/2}\Gamma(k/2)} \exp(y)^{k/2-1} \exp(-\exp(y)/2) \cdot \exp(y) \quad (24a)$$

$$= \frac{1}{2^{k/2}\Gamma(k/2)} \exp(y)^{k/2} \exp(-\exp(y)/2) \quad (24b)$$

$$= \exp \left[\frac{k}{2}y - \frac{\exp(y)}{2} - \log(2^{k/2}\Gamma(k/2)) \right] \quad (24c)$$

with $h(y) = 1$, $\phi(y) = (y, \exp(y))$, $\eta = (k/2)$ and $Z(k) = \log(2^{k/2}\Gamma(k/2))$.

8.2.1 Laplace approximation of the log-transformed Chi-squared distribution

$$\begin{aligned}
\text{log-pdf: } & \frac{k}{2}y - \frac{\exp(y)}{2} - \log(2^{k/2}\Gamma(k/2)) \\
\text{1st derivative: } & \frac{k}{2} - \frac{\exp(y)}{2} \\
\text{mode: } & k/2 - \frac{\exp(y)}{2} = 0 \Leftrightarrow y = \log(k) \\
\text{2nd derivative: } & -\frac{\exp(y)}{2} \\
\text{insert mode: } & -\frac{\exp(y)}{2} = -k/2 \\
\text{invert and times -1: } & \sigma^2 = 2/k
\end{aligned}$$

which yields the Laplace Approximation $q(y) = \mathcal{N}(y; \mu = \log(k), \sigma^2 = 2/k)$.

8.2.2 The Bridge for log-transform

$$\mu = \log(k) \quad (25a)$$

$$\sigma^2 = 2/k \quad (25b)$$

$$k = \exp(\mu) \quad (25c)$$

$$k = 2/\sigma^2 \quad (25d)$$

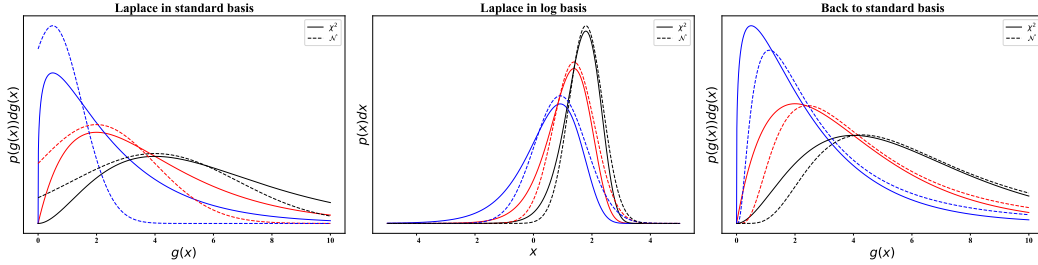

Figure 7: Chi-squared log bridge

8.3 Sqrt-Transformed Chi-squared distribution

we transform the distribution with $g(x) = \sqrt{x}$, i.e. $x(y) = g^{-1}(x) = y^2$. The new pdf becomes

$$\chi_{Y_s,qrt}^2(y, k) = \frac{1}{2^{k/2}\Gamma(k/2)} y^{2(k/2-1)} \exp(-y^2/2) \cdot 2y \quad (26a)$$

$$= \frac{1}{2^{k/2}\Gamma(k/2)} y^k \exp(-\frac{y^2}{2}) \quad (26b)$$

$$= \exp \left[k \log(y) - \frac{y^2}{2} - \log(2^{k/2}\Gamma(k/2)) \right] \quad (26c)$$

with $h(y) = 1, \phi(y) = (\log(y), y^2), w = (k, 1/2)$ and $Z(k) = \log(2^{k/2}\Gamma(k/2))$. Note that we drop a factor of 2 because of the explanation given in Section ??.

8.3.1 Laplace approximation of the sqrt-transformed Chi-squared distribution

$$\text{log-pdf: } (k \log(y) - \frac{y^2}{2} - \log(2^{k/2} \Gamma(k/2)))$$

$$\text{1st derivative: } \frac{k}{x} - y$$

$$\text{mode: } \frac{k}{x} - y = 0 \Leftrightarrow y = \sqrt{k}$$

$$\text{2nd derivative: } -\frac{k}{y^2} - 1$$

$$\text{insert mode: } -\frac{k}{k} - 1 = -2$$

$$\text{invert and times -1: } \sigma^2 = 1/2$$

8.3.2 The Bridge for sqrt-transform

$$\mu = \sqrt{k} \quad (27a)$$

$$\sigma^2 = 1/2 \quad (27b)$$

$$k = \mu^2 \quad (27c)$$

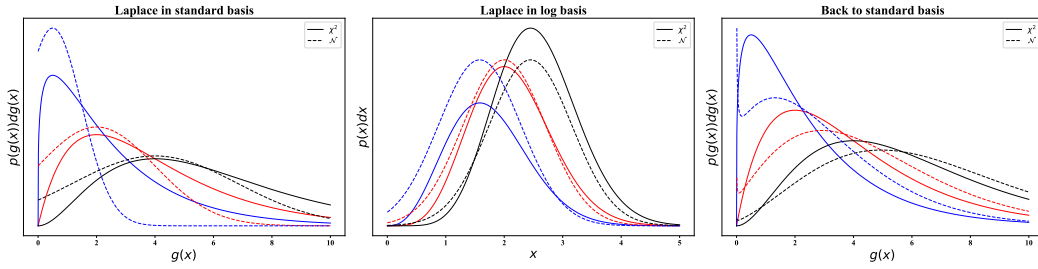

Figure 8: Chi-squared sqrt-bridge

9 Beta Distribution

9.1 Standard Beta Distribution

The pdf of the Beta distribution in the standard basis is

$$\mathcal{B}(x, \alpha, \beta) = \frac{x^{(\alpha-1)} \cdot (1-x)^{(\beta-1)}}{B(\alpha, \beta)} \quad (28a)$$

$$= \exp[(\alpha-1) \log(x) + (\beta-1) \log(1-x) - \log(B(\alpha, \beta)))] \quad (28b)$$

$$= \frac{1}{x(1-x)} \exp[\alpha \log(x) + \beta \log(1-x) - \log(B(\alpha, \beta)))] \quad (28c)$$

with $h(x) = \frac{1}{x(1-x)}$, $\phi(x) = (\log(x), \log(1-x))$, $w = (\alpha, \beta)$ and $Z(\alpha, \beta) = \log(B(\alpha, \beta))$ where $B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$ and $\Gamma(x)$ is the Gamma function.

9.1.1 Laplace approximation of the standard Beta distribution

To get the Laplace approximation we need the mode and Hessian. To get the mode we use the first derivative of the log-pdf and set it to zero. To get the Covariance we use the Hessian at the mode, multiply it with -1 and invert it.

$$\begin{aligned}
\text{log-pdf: } & \log \left(\frac{x^{(\alpha-1)} \cdot (1-x)^{(\beta-1)}}{B(\alpha, \beta)} \right) \\
& = (\alpha-1) \log(x) + (\beta-1) \log(1-x) - \log(B(\alpha, \beta)) \\
\text{1st derivative: } & \frac{(\alpha-1)}{x} - \frac{(\beta-1)}{1-x} \\
\text{mode: } & \frac{(\alpha-1)}{x} - \frac{(\beta-1)}{1-x} = 0 \Leftrightarrow x = \frac{\alpha-1}{\alpha+\beta-2} \\
\text{2nd derivative: } & \frac{\alpha-1}{x^2} + \frac{\beta-1}{(1-x)^2} \\
\text{insert mode: } & \frac{\alpha-1}{\frac{\alpha-1}{\alpha+\beta-2}} + \frac{\beta-1}{(1-\frac{\alpha-1}{\alpha+\beta-2})^2} = \frac{(\alpha+\beta-2)^3}{(\alpha-1)(\beta-1)} \\
\text{invert: } & \frac{(\alpha-1)(\beta-1)}{(\alpha+\beta-2)^3}
\end{aligned}$$

The Beta distribution in standard basis is therefore approximated by $N(\mu = \frac{\alpha-1}{\alpha+\beta-2}, \sigma^2 = \frac{(\alpha-1)(\beta-1)}{(\alpha+\beta-2)^3})$.

9.2 Logit-Transform of the Beta distribution

We transform the Beta distribution using $g(x) = \log(\frac{x}{1-x})$. Therefore $x(y) = g^{-1}(y) = \sigma(y) = \frac{1}{1+\exp(-y)}$. This yields the following pdf

$$\begin{aligned}
\mathcal{B}_{Y_{\text{logit}}}(y, \alpha, \beta) &= \frac{1}{\sigma(y)(1-\sigma(y))} \exp[\alpha \log(\sigma(y)) + \beta \log(1-\sigma(y)) - \log(B(\alpha, \beta))] \cdot (\sigma(y)(1-\sigma(y))) \\
&= \exp[\alpha \log(\sigma(y)) + \beta \log(1-\sigma(y)) - \log(B(\alpha, \beta))]
\end{aligned}
\tag{29a}$$

$$\tag{29b}$$

Which has $h(y) = 1$, $\phi(y) = (\log(\sigma(y)), \log(1-\sigma(y)))$, $w = (\alpha, \beta)$ and $Z(\alpha, \beta) = \log(B(\alpha, \beta))$.

9.2.1 Laplace approximation of the logit transformed Beta distribution

$$\begin{aligned}
\text{log-pdf: } & \log \left(\frac{\sigma(y)^\alpha \cdot (1-\sigma(y))^\beta}{B(\alpha, \beta)} \right) \\
& = \alpha \log(\sigma(y)) + \beta \log(1-\sigma(y)) - \log(B(\alpha, \beta)) \\
\text{1st derivative: } & \alpha(1-\sigma(y)) - \beta\sigma(y) \\
\text{mode: } & \alpha(1-\sigma(y)) - \beta\sigma(y) = 0 \Leftrightarrow y = \log\left(\frac{\alpha}{\beta}\right) \\
\text{2nd derivative: } & (\alpha+\beta)\sigma(y)(1-\sigma(y)) \\
\text{insert mode: } & (\alpha+\beta)\sigma(-\log(\frac{\beta}{\alpha}))(1-\sigma(-\log(\frac{\beta}{\alpha}))) = \frac{\alpha\beta}{\alpha+\beta} \\
\text{invert: } & \frac{\alpha+\beta}{\alpha\beta}
\end{aligned}$$

The Laplace approximation is therefore given by $\mathcal{N}(y; \mu = \log(\frac{\alpha}{\beta}), \sigma^2 = \frac{\alpha+\beta}{\alpha\beta})$.

9.2.2 The Bridge for the logit transformation

$$\mu = \log\left(\frac{\alpha}{\beta}\right) \quad (30a)$$

$$\sigma^2 = \frac{\alpha + \beta}{\alpha\beta} \quad (30b)$$

$$\alpha = \frac{\exp(\mu) + 1}{\sigma^2} \quad (30c)$$

$$\alpha = \frac{\exp(-\mu) + 1}{\sigma^2} \quad (30d)$$

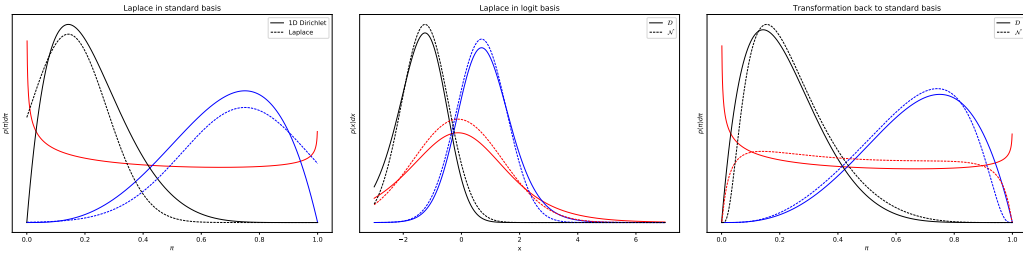

Figure 9: beta logit bridge

10 Dirichlet Distribution

10.1 Standard Dirichlet distribution

The pdf for the Dirichlet distribution in the standard basis (i.e. probability space) is

$$\text{Dir}(\boldsymbol{\pi}|\boldsymbol{\alpha}) = \frac{\Gamma\left(\sum_{k=1}^K \alpha_k\right)}{\prod_{k=1}^K \Gamma(\alpha_k)} \prod_{k=1}^K \pi_k^{\alpha_k-1} \quad (31a)$$

$$= \frac{1}{B(\boldsymbol{\alpha})} \prod_{k=1}^K \pi_k^{\alpha_k-1} \quad (31b)$$

$$= \exp\left[\sum_k (\alpha_k - 1) \log(\pi_k) - \log(B(\boldsymbol{\alpha}))\right] \quad (31c)$$

$$= \frac{1}{\prod_k \pi_k} \exp\left[\sum_k \alpha_k \log(\pi_k) - \log(B(\boldsymbol{\alpha}))\right] \quad (31d)$$

$$(31e)$$

with sufficient statistics $\phi(x_i) = \log(x_i)$, natural parameters $w_i = \alpha_i$, base measure $h(x) = \prod_k x_k$, and partition function $Z(w) = \log(B(\boldsymbol{\alpha}))$.

10.1.1 Laplace approximation of the standard Dirichlet distribution

$$\begin{aligned}
\text{log-pdf: } f &= \sum_k \alpha_k \log(\pi_k) - \log(B(\alpha)) \\
\text{1st derivative: } \frac{\partial f}{\partial x_i} &= \frac{\alpha_i - 1}{x_i} \\
\text{mode: } x_i &= \frac{(\alpha_i - 1)}{\sum_k \alpha_k} \\
\text{2nd derivative: } \frac{\partial^2 f}{\partial x_i \partial x_j} &= -\delta_{ij} \frac{(\alpha_i - 1)}{x_i^2} \\
\text{insert mode: } &-\delta_{ij} \frac{(\sum_k \alpha_k)^2}{(\alpha_i - 1)} \\
\text{invert and times -1: } \Sigma_{ij} &= \delta_{ij} \frac{\alpha_i - 1}{(\sum_k \alpha_k)^2}
\end{aligned}$$

Which yields a diagonal Covariance matrix for the Laplace approximation.

10.2 Softmax-Transform of the Dirichlet distribution

We aim to transform the basis of this distribution from base \mathbf{y} via the softmax transform to be in the new base π :

$$\pi_k(\mathbf{y}) := \frac{\exp(y_k)}{\sum_{l=1}^K \exp(y_l)}, \quad (32)$$

TODO:David J. MacKay has already done a transformation for the determinant but in a slightly different fashion.

The softmax transform has no analytic inverse $\pi_k^{-1}(y)$ but it is not necessary for our computation since we assume $\pi(y)$ to be the inverse transformation already (i.e. $g^{-1}(y)$). However, our transformation is from a variable in \mathbb{R}^d (which has d degrees of freedom) to a variable that is in \mathbb{P}^d (which has $d - 1$ degrees of freedom). To account for the difference in size of the two spaces we create a helper variable for the transformation as described in the following.

We want to transform K variables y_i from \mathbb{R}^d to $\tau_i = \exp(y_i)$. For τ_i to be equal to π_i we need to ensure that it sums to 1, $u = \sum_i \tau_i = 1$. With the helper-variable u our variable transform $g(\pi, u)$ becomes

$$p_{y,u}(\pi(y), u) = p_{\pi,u}(\pi(y), u) |\det g(\pi(y), u)| \quad (33)$$

with

$$|\det g(\pi(y), u)| = \left| \det \begin{pmatrix} \frac{\partial \tau_1}{\partial y_1} & \cdots & \frac{\partial \tau_K}{\partial y_1} & \frac{\partial u}{\partial y_1} \\ \vdots & \ddots & \vdots & \vdots \\ \frac{\partial \tau_1}{\partial y_K} & \cdots & \frac{\partial \tau_K}{\partial y_K} & \frac{\partial u}{\partial y_K} \\ \frac{\partial \tau_1}{\partial u} & \cdots & \frac{\partial \tau_K}{\partial u} & \frac{\partial u}{\partial u} \end{pmatrix} \right| \quad (34a)$$

$$= \left| \det \begin{pmatrix} \tau_1 = \exp(y_1) & \cdots & 0 & \tau_1 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & \tau_K & \tau_K \\ 0 & \cdots & 0 & 1 \end{pmatrix} \right| \quad (34b)$$

$$= \prod_i^K \tau_i \quad (34c)$$

To get $p_y(\pi(y))$ we have to integrate out u .

$$p_y(\pi(y)) = \int_{-\infty}^{\infty} p_{\pi,u}(\pi(y), u) |\det g(\pi, u)| du \quad (35a)$$

$$= \int_{-\infty}^{\infty} p_{\pi}(\pi(y)) \prod_i^K \tau_i du \quad (35b)$$

$$= p_{\pi}(\pi(y)) \int_0^{\infty} \prod_i^K \tau_i \delta(u - 1) du \quad (35c)$$

$$= p_{\pi}(\pi(y)) \int_0^{\infty} \prod_i^K \tau_i \frac{u}{u} \delta(u - 1) du \quad (35d)$$

$$= p_{\pi}(\pi(y)) \int_0^{\infty} \underbrace{\prod_i^K \pi_i u}_{f(u)} \delta(u - 1) du \quad (35e)$$

$$= p_{\pi}(\pi(y)) \cdot \prod_i^K \pi_i(y) \quad (35f)$$

$$= \frac{1}{\prod_k \pi_k(y)} \exp \left[\sum_k \alpha_k \log(\pi_k(y)) - \log(B(\alpha)) \right] \prod_k^K \pi_k(y) \quad (35g)$$

$$= \exp \left[\sum_k \alpha_k \log(\pi(y_k)) - \log(B(\alpha)) \right] \quad (35h)$$

where we used the fact that $u > 0$ since its a sum of exponentials, $\frac{\tau_i(y)}{u} = \pi_i(y)$, and multiplied with $\delta(u - 1)$ since this transformation is only valid if $\sum_i \tau_i = u = 1$ because otherwise it is not a probability space. Additionally, we use

$$\int_{-\infty}^{\infty} f(x) \delta(x - t) dx = f(t) \quad (36)$$

which is known as the shifting property or sampling property of the Dirac delta function δ . Using all of the above we get the pdf of the Dirichlet distribution in the new basis \mathbf{y} :

$$\text{Dir}_{\mathbf{y}}(\pi(\mathbf{y})|\alpha) := \frac{\Gamma\left(\sum_{k=1}^K \alpha_k\right)}{\prod_{k=1}^K \Gamma(\alpha_k)} \prod_{k=1}^K \pi_k(\mathbf{y})^{\alpha_k} \quad (37a)$$

$$= \exp \left[\sum_k \alpha_k \log(\pi(y_k)) - \log(B(\alpha)) \right] \quad (37b)$$

with sufficient statistics $\phi(y_i) = \log(\pi_i(y))$, natural parameters $w_i = \alpha_i$, base measure $h(y) = 1$ and normalizing constant $Z = \log(B(\alpha))$.

10.2.1 Laplace approximation of the softmax-transformed Dirichlet distribution

TODO: mention that this has been done by Philipp in his PhD thesis.

Through the figures of the 1D Dirichlet approximation in the main paper we have already established that the mode of the Dirichlet lies at the mean of the Gaussian distribution and therefore $\pi(\mathbf{y}) = \frac{\alpha}{\sum_i \alpha_i}$.

Additionally, the elements of \mathbf{y} must sum to zero. These two constraints combined yield only one possible solution for $\boldsymbol{\mu}$.

$$\mu_k = \log \alpha_k - \frac{1}{K} \sum_{l=1}^K \log \alpha_l \quad (38)$$

Calculating the covariance matrix $\boldsymbol{\Sigma}$ is more complicated but layed out in the following. The logarithm of the Dirichlet is, up to additive constants

$$\log p_y(y|\alpha) = \sum_k \alpha_k \pi_k \quad (39)$$

Using π_k as the softmax of \mathbf{y} as shown in Equation 32 we can find the elements of the Hessian \mathbf{L}

$$L_{kl} = \hat{\alpha}(\delta_{kl}\hat{\pi}_k - \hat{\pi}_k\hat{\pi}_l) \quad (40)$$

where $\hat{\alpha} := \sum_k \alpha_k$ and $\hat{\pi} = \frac{\alpha_k}{\hat{\alpha}}$ for the value of $\boldsymbol{\pi}$ at the mode. Analytically inverting \mathbf{L} is done via a lengthy derivation using the fact that we can write $\mathbf{L} = \mathbf{A} + \mathbf{X}\mathbf{B}\mathbf{X}^\top$ and inverting it with the Schur-complement. This process results in the inverse of the Hessian

$$L_{kl}^{-1} = \delta_{kl} \frac{1}{\alpha_k} - \frac{1}{K} \left[\frac{1}{\alpha_k} + \frac{1}{\alpha_l} - \frac{1}{K} \left(\sum_u \frac{1}{\alpha_u} \right) \right] \quad (41)$$

We are mostly interested in the diagonal elements, since we desire a sparse encoding for computational reasons and we otherwise needed to map a $K \times K$ covariance matrix to a $K \times 1$ Dirichlet parameter vector which would be a very overdetermined mapping. Note that K is a scalar not a matrix. The diagonal elements of $\boldsymbol{\Sigma} = \mathbf{L}^{-1}$ can be calculated as

$$\Sigma_{kk} = \frac{1}{\alpha_k} \left(1 - \frac{2}{K} \right) + \frac{1}{K^2} \sum_l \frac{1}{\alpha_l}. \quad (42)$$

To invert this mapping we transform Equation 38 to

$$\alpha_k = e^{\mu_k} \prod_l \alpha_l^{1/K} \quad (43)$$

by applying the logarithm and re-ordering some parts. Inserting this into Equation 42 and re-arranging yields

$$\prod_l \alpha_l^{1/K} = \frac{1}{\Sigma_{kk}} \left[e^{-\mu} \left(1 - \frac{2}{K} \right) + \frac{1}{K^2} \sum_u e^{-\mu_u} \right] \quad (44)$$

which can be re-inserted into Equation 43 to give

$$\alpha_k = \frac{1}{\Sigma_{kk}} \left(1 - \frac{2}{K} + \frac{e^{-\mu_k}}{K^2} \sum_l e^{-\mu_l} \right) \quad (45)$$

which is the final mapping. With Equations 38 and 42 we are able to map from Dirichlet to Gaussian and with Equation 45 we are able to map the inverse direction.

10.2.2 The Bridge for the inverse-softmax transform

In summary we get the following forward and backward transformations between $\mathbf{y} \in \mathbb{R}^d$ and $\pi \in \mathbb{P}^d$.

$$\mu_k = \log \alpha_k - \frac{1}{K} \sum_{l=1}^K \log \alpha_l, \quad (46a)$$

$$\Sigma_{k\ell} = \delta_{k\ell} \frac{1}{\alpha_k} - \frac{1}{K} \left[\frac{1}{\alpha_k} + \frac{1}{\alpha_\ell} - \frac{1}{K} \sum_{u=1}^K \frac{1}{\alpha_u} \right]. \quad (46b)$$

The corresponding derivations require care because the Gaussian parameter space is evidently larger than that of the Dirichlet and not fully identified by the transformation. A pseudo-inverse of this map was provided by ?. It maps the Gaussian parameters to those of the Dirichlet as

$$\alpha_k = \frac{1}{\Sigma_{kk}} \left(1 - \frac{2}{K} + \frac{e^{\mu_k}}{K^2} \sum_{l=1}^K e^{-\mu_l} \right) \quad (47)$$

11 Wishart Distribution

11.1 Interlude: Box-product and Kronecker-product

Kronecker-product: $A \otimes B \in \mathbb{R}^{(m_1 m_2) \times (n_1 n_2)}$ is defined by $(A \otimes B)_{(i-1)m_2+j, (k-1)n_2+l} = a_{ik} b_{jl} = (A \otimes B)_{(ij)(kl)}$.

Box-product: $A \boxtimes B \in \mathbb{R}^{(m_1 m_2) \times (n_1 n_2)}$ is defined by $(A \boxtimes B)_{(i-1)m_2+j, (k-1)n_1+l} = a_{il} b_{jk} = (A \boxtimes B)_{(ij)(kl)}$.

I found this box-product only in two sources, one of which is this: <https://researcher.watson.ibm.com/researcher/files/us-pederao/ADTalk.pdf> but it generally seems to be very helpful for matrix derivations with transposed matrices.

11.2 Standard Wishart distribution

the pdf of the Wishart is

$$\mathcal{W}(X; n, p, V) = \frac{1}{2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right)} |\mathbf{X}|^{(n-p-1)/2} e^{-(1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{X})} \quad (48a)$$

$$= \exp \left[(n-p-1)/2 \log(|X|) - (1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{X}) - \log \left(2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right) \right) \right] \quad (48b)$$

$$= \frac{1}{X^{\frac{1}{2}}} \exp \left[(n-p)/2 \log(|X|) - (1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{X}) - \log \left(2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right) \right) \right] \quad (48c)$$

with $h(X) = 1/X^{\frac{1}{2}}$, $\phi(X) = (\log(X), X)$, $w = ((n-p)/2, V^{-1})$ and $Z(n, p, V) = \log \left(2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right) \right)$.

11.2.1 Laplace Approximation of the standard Wishart distribution

Using $\frac{\partial \det(X)}{\partial X} = \det(X)(X^{-1})^\top$ and $\frac{\partial}{\partial X} \text{Tr}(AX) = A^\top$ we can calculate the mode by setting the first derivative of the log-pdf to zero

$$\begin{aligned}
\frac{\partial \log \mathcal{W}(X; n, p, V)}{\partial X} &= \frac{(n-p-1) \det(X)(X^{-\top})}{2 \det(X)} - \frac{V^{-\top}}{2} \\
&\Rightarrow 0 = \frac{(n-p-1)X^{-1}}{2} - \frac{V^{-1}}{2} \\
&\Leftrightarrow \frac{(n-p-1)X^{-1}}{2} = \frac{V^{-1}}{2} \\
&\Leftrightarrow X = (n-p-1)V
\end{aligned}$$

Using the fact that the root of a symmetric matrix is symmetric and $\frac{\partial X^{-1}}{\partial X} = -X^{-1} \otimes X^{-1}$ we get

$$\frac{\partial^2 \log f(X; n, p, V)}{\partial^2 X} = -\frac{(n-p-1)}{2} X^{-1} \otimes X^{-1}$$

Using $(\alpha A)^{-1} = \alpha^{-1} A^{-1}$, the linearity of the Kronecker product to pull out scalars and $X^{-1} \otimes X^{-1} = (X \otimes X)^{-1}$ to insert the mode and invert we get:

$$\begin{aligned}
-\frac{(n-p-1)}{2} X^{-1} \otimes X^{-1} &= -\frac{(n-p-1)}{2} \frac{1}{(n-p-1)} V^{-1} \otimes \frac{1}{(n-p-1)} V^{-1} \\
&= -\frac{1}{2(n-p-1)} (V \otimes V)^{-1} \\
&\Rightarrow \Sigma = 2(n-p-1)(V \otimes V)
\end{aligned}$$

In summary, the Laplace approximation of a Wishart distribution in the standard basis is $\mathcal{N}(X; (n-p-1)V, 2(n-p-1)(V \otimes V))$, where the representation of the symmetric positive definite matrices has been changed from $\mathbb{R}^{n \times n}$ to \mathbb{R}^{n^2} .

11.3 Logm-Transformed Wishart distribution

we transform the distribution with $g(X) = \log m(X)$, i.e. $X(Y) = g^{-1}(X) = \exp m(Y)$, where $\exp m(Y)$ is the matrix exponential and $\log m(Y)$ is the matrix logarithm of Y . The new pdf becomes

$$\mathcal{W}_{\log m}(Y; n, p, V) = \frac{1}{2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right)} |\exp m \mathbf{Y}|^{(n-p-1)/2} e^{-(1/2) \text{tr}(\mathbf{V}^{-1} \exp m \mathbf{Y})} \cdot |\exp m Y| \quad (49a)$$

$$= \frac{1}{2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right)} |\exp m \mathbf{Y}|^{(n-p+1)/2} e^{-(1/2) \text{tr}(\mathbf{V}^{-1} \exp m \mathbf{Y})} \quad (49b)$$

$$= \exp \left[C + \frac{(n-p+1)}{2} \log(|\exp m \mathbf{Y}|) - \frac{1}{2} \text{tr}(\mathbf{V}^{-1} \exp m \mathbf{Y}) \right] \quad (49c)$$

with $h(Y) = Y^{\frac{1}{2}}, \phi(Y) = (Y, \exp m Y), w = (n-p), V^{-1}$ and $Z(n, p, V) = \log \left(2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right) \right)$.

11.3.1 Laplace Approximation of the logm-transformed Wishart distribution

To compute the first derivative we use the following

$$\frac{\partial \log(\det(\exp m(Y)))}{\partial Y} = \frac{\partial \log(\det(\exp m(Y)))}{\partial \det(\exp m(Y))} \cdot \frac{\partial \det(\exp m(Y))}{\partial \exp m(Y)} \cdot \frac{\partial \exp m(Y)}{\partial Y} \quad (50)$$

$$= \frac{1}{\det(\exp m(Y))} \cdot \det(\exp m(Y)) \exp m(Y)^{-\top} \cdot \exp m(Y) \quad (51)$$

$$= I_p \quad (52)$$

where I_p is the identity matrix of size p and we use the fact that the matrix logarithm of a symmetric matrix is symmetric, implying $\text{expm}(Y)^{-\top} = \text{expm}(Y)^{-1}$. With this we get the first derivative

$$\frac{\partial \log W_{\log}}{\partial Y} = \frac{\partial}{\partial Y} \left[C + \frac{(n-p+1)}{2} \log(|\text{expm } \mathbf{Y}|) - \frac{1}{2} \text{tr}(\mathbf{V}^{-1} \text{expm } \mathbf{Y}) \right] \quad (53a)$$

$$= \frac{(n-p+1)}{2} I_p - \frac{1}{2} V^{-1} \text{expm } \mathbf{Y} \quad (53b)$$

By setting this to zero we get a mode of

$$0 = \frac{(n-p+1)}{2} I_p - \frac{1}{2} V^{-1} \text{expm } \mathbf{Y} \quad (54a)$$

$$\Leftrightarrow (n-p+1) I_p = V^{-1} \text{expm } \mathbf{Y} \quad (54b)$$

$$\Leftrightarrow Y = \log m((n-p+1)V) \quad (54c)$$

For the second derivative we use the fact that

$$\frac{\partial (B \text{expm}(Y))_{kl}}{\partial Y_{ij}} = \delta_{jl} (B \text{expm}(Y))_{ki} \quad (55a)$$

$$\Leftrightarrow \frac{\partial B \text{expm}(Y)}{\partial Y} = (B \text{expm}(Y) \otimes I_p) \quad (55b)$$

yielding

$$\frac{\partial^2 \log \mathcal{W}_{\log m}}{\partial^2 Y} = \frac{\partial \log \mathcal{W}_{\log m}}{\partial Y} \frac{(n-p+1)}{2} I_p - \frac{1}{2} V^{-1} \text{expm } \mathbf{Y} \quad (56a)$$

$$= -\frac{1}{2} (V^{-1} \text{expm } \mathbf{Y} \otimes I_p) \quad (56b)$$

$$\stackrel{\text{mode}}{\Rightarrow} -\frac{1}{2} ((n-p+1) V^{-1} V \otimes I_p) \quad (56c)$$

$$= -\frac{(n-p+1)}{2} (I_p \otimes I_p) \quad (56d)$$

$$\Leftrightarrow \Sigma = \frac{2}{n-p+1} I_{p^2} \quad (56e)$$

where I_{p^2} is an Identity matrix of size p^2 .

11.3.2 The Bridge for logm-transform

μ and Σ are already given by the Laplace approximation. Inverting the mode yields an estimate for V .

$$\mu = \log m((n-p+1)V) \Leftrightarrow \text{expm}(\mu) = (n-p+1)V \Leftrightarrow V = \frac{\text{expm}(\mu)}{(n-p+1)} \quad (57)$$

where μ and V are reshaped to a matrix of size $p \times p$. In summary this yields

$$\mu = \log m((n-p+1)V) \quad (58a)$$

$$\Sigma = \frac{2}{n-p+1} I_{p^2} \quad (58b)$$

$$V = \frac{\text{expm}(\mu)}{(n-p+1)} \quad (58c)$$

$$n = ? \quad (58d)$$

11.4 Sqrtm-Transformed Wishart distribution

we transform the distribution with $g(X) = \text{sqrtm}(X) = X^{\frac{1}{2}}$, i.e. $X(Y) = g^{-1}(X) = Y^2$, where $\text{sqrtm}(Y)$ is the square root of the matrix. The new pdf becomes

$$\mathcal{W}_{\text{sqrtm}}(Y; n, p, V) = \frac{1}{2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right)} |\mathbf{Y}^2|^{(n-p-1)/2} e^{-(1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{Y}^2)} \cdot |2Y| \quad (59a)$$

$$= \frac{1}{2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right)} |\mathbf{Y}|^{2(n-p-1)/2} e^{-(1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{Y}^2)} \cdot 2^p |Y| \quad (59b)$$

$$= \frac{1}{2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right)} |\mathbf{Y}|^{(n-p)} e^{-(1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{Y}^2)} \quad (59c)$$

$$= \exp \left[(n-p) \log(|Y|) - (1/2) \text{tr}(\mathbf{V}^{-1} \mathbf{Y}^2) - \log \left(2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right) \right) \right] \quad (59d)$$

with $h(Y) = 1, \phi(Y) = (\log(Y), Y^2), \eta = ((n-p), V^{-1})$ and $Z(n, p, V) = \log \left(2^{np/2} |\mathbf{V}|^{n/2} \Gamma_p\left(\frac{n}{2}\right) \right)$. We drop the 2^p because there are 2^p matrices that are a root of X as already explained in subsection TODO.

11.4.1 Laplace Approximation of the sqrtm-transformed Wishart distribution

Using $\frac{\partial \det(Y)}{\partial Y} = \det(Y)(Y^{-1})^\top$ and $\frac{\partial}{\partial Y} \text{Tr}(AY^2) = (AY + YA)^T$ we can calculate the mode by setting the first derivative of the log-pdf to zero

$$\frac{\partial \log \mathcal{W}_{\text{sqrtm}}(Y; n, p, V)}{\partial Y} = \frac{(n-p) \det(Y)(Y^{-1})^\top}{\det(Y)} - \frac{(V^{-1}Y + YV^{-1})^\top}{2} \quad (60a)$$

$$\Rightarrow 0 = (n-p)Y^{-\top} - \frac{(V^{-1}Y + YV^{-1})^\top}{2} \quad (60b)$$

$$\Leftrightarrow (n-p)Y^{-\top} = \frac{(V^{-1}Y + YV^{-1})^\top}{2} \quad (60c)$$

$$\Leftrightarrow (n-p)Y^{-1} = \frac{(V^{-1}Y + YV^{-1})}{2} \quad (60d)$$

$$\Leftrightarrow Y = ??? \quad (60e)$$

THIS IS WHERE SOLVING FOR Y GETS COMPLICATED. Maybe we can rewrite it with Kronecker products and vectorized matrices like for the Sylvester equation and these laws [https://en.wikipedia.org/wiki/Vectorization_\(mathematics\)#Compatibility_with_Kronecker_products](https://en.wikipedia.org/wiki/Vectorization_(mathematics)#Compatibility_with_Kronecker_products).

So far I have found the following relationships that don't get me any further to the solution of Y :

$$\begin{aligned} (n-p)Y^{-1} &= \frac{(V^{-1}Y + YV^{-1})}{2} \\ \Leftrightarrow C &= BY + YBY \\ \Leftrightarrow C &= (I_p \otimes BY) \text{vec} Y + (B^T Y^T \otimes I_p) \text{vec} Y \\ \Leftrightarrow C &= (B^T Y^T \oplus BY) \text{vec} Y \\ \Leftrightarrow C &= (BY \oplus BY) \text{vec} Y \end{aligned}$$

Computing the second derivative by using $\frac{\partial}{\partial Y} Y^{-1} = -Y^{-1} \otimes Y^{-1}$, $\frac{\partial}{\partial Y} (AY + YA)^\top = I \boxtimes A + A \boxtimes I$. For simplicity we approximate the mode with $Y = \sqrt{(n-p)V}$.

$$\frac{\partial^2 \log \mathcal{W}_{\text{sqrtn}}(Y; n, p, V)}{\partial^2 Y} = \frac{\partial}{\partial Y} \left[(n-p)Y^{-\top} - \frac{(V^{-1}Y + YV^{-1})^\top}{2} \right] \quad (61a)$$

$$= -(n-p)(Y^{-\top} \otimes Y^{-1}) + \frac{1}{2}(I_p \boxtimes V^{-1} + V^{-1} \boxtimes I_p) \quad (61b)$$

$$\stackrel{\text{mode}}{\Rightarrow} -(n-p) \left[\sqrt{\frac{1}{(n-p)}} V^{-\frac{1}{2}} \otimes \sqrt{\frac{1}{(n-p)}} V^{-\frac{1}{2}} \right] + \frac{1}{2} [I_p \boxtimes V^{-1} + V^{-1} \boxtimes I_p] \quad (61c)$$

$$= - \left(V^{-\frac{1}{2}} \otimes V^{-1} \right) + \frac{1}{2} [I_p \boxtimes V^{-1} + V^{-1} \boxtimes I_p] \quad (61d)$$

$$\stackrel{-1}{\Rightarrow} \left(V^{-\frac{1}{2}} \otimes V^{-\frac{1}{2}} \right) - \frac{1}{2} [I_p \boxtimes V^{-1} + V^{-1} \boxtimes I_p] \quad (61e)$$

$$\Rightarrow \Sigma = \left[V^{-\frac{1}{2}} \otimes V^{-\frac{1}{2}} - \frac{1}{2} (I_p \boxtimes V^{-1} + V^{-1} \boxtimes I_p) \right]^{-1} \quad (61f)$$

$$(61g)$$

We can assume that Y is symmetric because the root of a symmetric positive definite matrix is symmetric. This is the solution ONLY if we assume that the mode is given by $Y = \sqrt{(n-p)V}^{\frac{1}{2}}$.

11.4.2 The Bridge for sqrtn-transform

we use $\mu = ((n-p)V)^{\frac{1}{2}} \Leftrightarrow \mu^2 = (n-p)V \Leftrightarrow V = \frac{\mu^2}{(n-p)}$. Remember that μ is reshaped to be the same size as V even though we usually think of it in vector-form.

$$\mu = ((n-p)V)^{\frac{1}{2}} \quad (62a)$$

$$\Sigma = \left[V^{-\frac{1}{2}} \otimes V^{-\frac{1}{2}} - \frac{1}{2} (I_p \boxtimes V^{-1} + V^{-1} \boxtimes I_p) \right]^{-1} \quad (62b)$$

$$V = \frac{\mu^2}{(n-p)} \quad (62c)$$

$$n = ? \quad (62d)$$

STRUGGLE: how to get n ?

INTERESTING: choosing $\Sigma = 1/4 \cdot (V^{\frac{1}{2}} \otimes V^{\frac{1}{2}})$ also yields pretty good results.

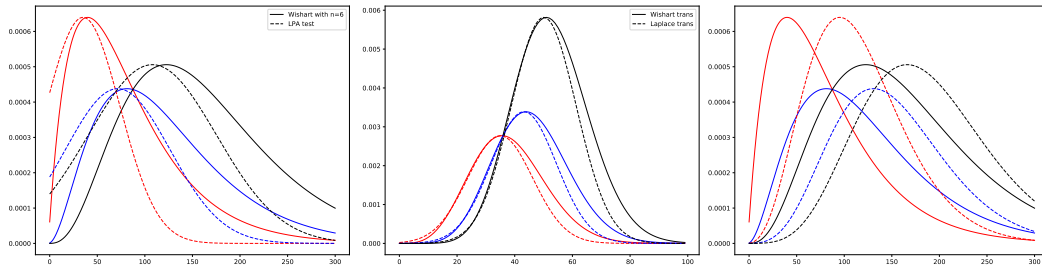

Figure 10: wishart comparison for sqrtn

12 Inverse Wishart Distribution

12.1 Standard Inverse Wishart distribution

the pdf of the Inverse Wishart is

$$\mathcal{IW}_{\mathbf{x}}(\mathbf{x}; \Psi, \nu) = \frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} |\mathbf{x}|^{-(\nu+p+1)/2} e^{-\frac{1}{2} \text{tr}(\Psi \mathbf{x}^{-1})} \quad (63a)$$

$$= \exp \left[-(\nu + p + 1)/2 \log(|x|) - \frac{1}{2} \text{tr}(\Psi x^{-1}) + \log\left(\frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})}\right) \right] \quad (63b)$$

with $h(X) = 1/X^{\frac{1}{2}}$, $\phi(X) = (\log(X), X^{-1})$, $w = (-(\nu + p)/2, \Psi)$ and $Z(n, p, V) = -\log\left(\frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})}\right)$.

12.1.1 Laplace Approximation of the standard inverse Wishart distribution

Using $\frac{\partial \det(X)}{\partial X} = \det(X)(X^{-1})^\top$ and $\frac{\partial}{\partial X} \text{tr}(AX)^{-1} = (X^{-1}AX^{-1})^\top$ we can calculate the mode by setting the first derivative of the log-pdf to zero:

$$\frac{\partial \log \mathcal{IW}_{\mathbf{x}}(\mathbf{X}; \Psi, \nu)}{\partial X} = \frac{-(\nu + p + 1) \det(X) X^{-\top}}{2 \det(X)} + \frac{(X^{-1} \Psi X^{-1})^\top}{2} \quad (64a)$$

$$= \frac{-(\nu + p + 1) X^{-\top}}{2} + \frac{(X^{-1} \Psi X^{-1})^\top}{2} \quad (64b)$$

$$\Rightarrow 0 = \frac{-(\nu + p + 1) X^{-\top}}{2} + \frac{(X^{-1} \Psi X^{-1})^\top}{2} \quad (64c)$$

$$\Leftrightarrow (\nu + p + 1) X^{-1} = X^{-1} \Psi X^{-1} \quad (64d)$$

$$\Leftrightarrow (\nu + p + 1) = X^{-1} \Psi \quad (64e)$$

$$\Leftrightarrow X = \frac{1}{\nu + p + 1} \Psi \quad (64f)$$

Using

$$\frac{\partial (XBX)_{kl}}{\partial X_{ij}} = \delta_{ki} (BX)_{lj} + \delta_{lj} (XB)_{ki} \quad (65)$$

$$\frac{\partial X^{-1}}{\partial X} = -(X^{-1} \otimes X^{-1}) \quad (66)$$

$$\frac{\partial (X^{-1}BX^{-1})}{\partial X} = \frac{\partial (X^{-1}BX^{-1})}{\partial X^{-1}} \frac{\partial X^{-1}}{\partial X} = -[\delta_{ki} (BX^{-1})_{lj} + \delta_{lj} (X^{-1}B)_{ki}] (X^{-1} \otimes X^{-1}) \quad (67)$$

$$(AB)^{-1} = B^{-1}A^{-1} \quad (68)$$

we can get the covariance matrix by inverting the Hessian and multiplying with -1.

$$\frac{\partial^2 \log f_{\mathbf{X}}(\mathbf{X}; \Psi, \nu)}{\partial^2 X} = \frac{(\nu + p + 1)}{2} (X^{-1} \otimes X^{-1})^\top - \frac{[\delta_{ki}(\Psi X^{-1})_{lj} + \delta_{lj}(X^{-1}\Psi)_{ki}]}{2} (X^{-1} \otimes X^{-1})^\top$$

(69a)

$$= \left\{ \frac{(\nu + p + 1)}{2} I_{n^2} - \frac{[\delta_{ki}(\Psi X^{-1})_{lj} + \delta_{lj}(X^{-1}\Psi)_{ki}]}{2} \right\} (X^{-1} \otimes X^{-1})^\top$$

(69b)

$$\stackrel{\text{insert mode}}{=} \left\{ \frac{(\nu + p + 1)}{2} I_{n^2} - \frac{[\delta_{ki}((\nu + p + 1)\Psi\Psi^{-1})_{lj} + \delta_{lj}((\nu + p + 1)\Psi^{-1}\Psi)_{ki}]}{2} \right\} (\nu + p + 1)^2 (\psi \otimes \psi)^\top$$

(69c)

$$= \left\{ \frac{(\nu + p + 1)}{2} I_{n^2} - \underbrace{\frac{[\delta_{ki}((\nu + p + 1)I_n)_{lj} + \delta_{lj}((\nu + p + 1)I_n)_{ki}]}{2}}_{=(\nu + p + 1)I_{n^2}} \right\} (\nu + p + 1)^2 (\psi \otimes \psi)^{-\top}$$

(69d)

$$= - \underbrace{\frac{1}{2}(\nu + p + 1)I_{n^2}}_A \underbrace{(\nu + p + 1)^2 (\psi \otimes \psi)^{-\top}}_B$$

(69e)

$$\stackrel{\text{invert}}{\Rightarrow} - \frac{1}{(\nu + p + 1)^2} (\psi \otimes \psi)^\top \frac{2}{(\nu + p + 1)} I_{n^2}$$

(69f)

$$\stackrel{\cdot -1}{\Rightarrow} \Sigma = \frac{2}{(\nu + p + 1)^3} (\Psi \otimes \Psi)^\top$$

(69g)

where I_n and I_n^2 are the identity matrix of size n and n^2 respectively. We can also ignore the transpose since we are dealing with symmetric positive definite matrices when it comes to the inverse Wishart distribution. This yields a multivariate Normal of the form $\mathcal{N}(X; \mu = \frac{1}{\nu + p + 1} \Psi, \Sigma = \frac{2}{(\nu + p + 1)^3} (\Psi \otimes \Psi)^\top)$.

12.2 Logm-Transformed inverse Wishart distribution

we transform the distribution with $g(X) = \log m(X)$, i.e. $X(Y) = g^{-1}(X) = \exp m(Y)$, where $\exp m(Y)$ is the matrix exponential. The new pdf becomes

$$\mathcal{IW}_{\log m}(\mathbf{Y}; \Psi, \nu) = \frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} |\exp m \mathbf{Y}|^{-(\nu + p + 1)/2} e^{-\frac{1}{2} \text{tr}(\Psi(\exp m \mathbf{Y})^{-1})} \cdot |\exp m(\mathbf{Y})| \quad (70a)$$

$$= \frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} |\exp m \mathbf{Y}|^{-(\nu + p - 1)/2} e^{-\frac{1}{2} \text{tr}(\Psi(\exp m \mathbf{Y})^{-1})} \quad (70b)$$

$$= \exp \left[C - (\nu + p - 1)/2 \log |\exp m \mathbf{Y}| - \frac{1}{2} \text{tr}(\Psi \exp m(-\mathbf{Y})) \right] \quad (70c)$$

with exponential family statistics $h(Y) = Y^{\frac{1}{2}}, \phi(Y) = (\log(\det(\exp m(Y))), \exp m(Y))$, $w = ((\nu + p)/2, \Psi)$ and $Z(n, p, V) = -\log \left(\frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} \right)$

12.2.1 Laplace Approximation of the logm-transformed inverse Wishart distribution

For the first derivative we use the same ideas as for the Wishart (TODO:link).

$$\frac{\partial \log \mathcal{IW}_{logm}}{\partial Y} = \frac{\partial}{\partial Y} - (\nu + p - 1)/2 \log |\expm \mathbf{Y}| - \frac{1}{2} \text{tr}(\mathbf{\Psi} \expm(-\mathbf{Y})) \quad (71a)$$

$$= -\frac{(\nu + p - 1)}{2} + \frac{1}{2} \mathbf{\Psi} \expm(-\mathbf{Y}) \quad (71b)$$

which yields the mode by setting it to zero and solving for Y .

$$0 = -\frac{(\nu + p - 1)}{2} + \frac{1}{2} \mathbf{\Psi} \expm(-\mathbf{Y}) \quad (72a)$$

$$\Leftrightarrow (\nu + p - 1)I_p = \mathbf{\Psi}(\expm(\mathbf{Y}))^{-1} \quad (72b)$$

$$\Leftrightarrow Y = \text{logm} \left(\frac{\mathbf{\Psi}}{n + p - 1} \right) \quad (72c)$$

For the second derivative we also use the same ideas as for the Wishart (TODO: link + rewrite).

$$\frac{\partial^2 \log \mathcal{IW}_{logm}}{\partial^2 Y} = \frac{\partial}{\partial Y} \left[-\frac{(\nu + p - 1)}{2} + \frac{1}{2} \mathbf{\Psi} \expm(-\mathbf{Y}) \right] \quad (73a)$$

$$= -\frac{1}{2} [\mathbf{\Psi} \expm(\mathbf{Y})^{-1} \otimes I_p] \quad (73b)$$

$$\stackrel{\text{mode}}{\Rightarrow} -\frac{1}{2} \left[\mathbf{\Psi} \frac{\mathbf{\Psi}^{-1}}{(\nu + p - 1)} \otimes I_p \right] \quad (73c)$$

$$= -\frac{1}{2(\nu + p - 1)} I_{p \times p} \quad (73d)$$

$$\Rightarrow \Sigma = 2(\nu + p - 1)I_{p \times p} \quad (73e)$$

This yields a multivariate Normal distribution $\mathcal{N} \left(Y; \mu = \text{logm} \left(\frac{\mathbf{\Psi}}{n + p - 1} \right), \Sigma = 2(\nu + p - 1)I_{p \times p} \right)$.

12.2.2 The Bridge for the logm-transformed inverse Wishart distribution

We get μ and Ψ from the Laplace approximation and determine V by inverting μ

$$\mu = \text{logm} \left(\frac{\mathbf{\Psi}}{n + p - 1} \right) \Leftrightarrow \expm(\mu) = \frac{\mathbf{\Psi}}{n + p - 1} \Leftrightarrow \mathbf{\Psi} = \expm(\mu)(n + p - 1) \quad (74a)$$

In summary:

$$\mu = \text{logm} \left(\frac{\mathbf{\Psi}}{n + p - 1} \right) \quad (75a)$$

$$\Sigma = 2(\nu + p - 1)I_{p \times p} \quad (75b)$$

$$\mathbf{\Psi} = (\nu + p - 1) \expm(\mu) \quad (75c)$$

$$\nu = ? \quad (75d)$$

where $\mathbf{\Psi}$ is reshaped to a $p \times p$ matrix.

12.3 Sqrtm-Transformed inverse Wishart distribution

we transform the distribution with $g(X) = \text{sqrtm}(X) = X^{\frac{1}{2}}$, i.e. $X(Y) = g^{-1}(X) = Y^2$, where $\text{sqrtm}(Y)$ is the square root of the matrix. The new pdf becomes

$$\mathcal{IW}_{\text{sqrtm}}(\mathbf{Y}; \Psi, \nu) = \frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} |\mathbf{Y}^2|^{-(\nu+p+1)/2} e^{-\frac{1}{2} \text{tr}(\Psi \mathbf{Y}^{-2})} |2Y| \quad (76a)$$

$$= \frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} |\mathbf{Y}|^{-(\nu+p+1)} e^{-\frac{1}{2} \text{tr}(\Psi \mathbf{Y}^{-2})} 2^p |Y| \quad (76b)$$

$$= \frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} |\mathbf{Y}|^{-(\nu+p)} e^{-\frac{1}{2} \text{tr}(\Psi \mathbf{Y}^{-2})} 2^p \quad (76c)$$

$$= \exp \left[-(\nu+p) \log(|Y|) - \frac{1}{2} \text{tr}(\Psi Y^{-2}) + \log(C) \right] \quad (76d)$$

with $h(Y) = 1$, $\phi(Y) = (\log(|Y|), Y^{-2})$, $w = (-(\nu+p), \Psi)$ and $Z(w) = \log \left(\frac{|\Psi|^{\nu/2}}{2^{\nu p/2} \Gamma_p(\frac{\nu}{2})} \right)$.

12.3.1 Laplace Approximation of the sqrtm-transformed inverse Wishart distribution

Using

$$\frac{\partial \text{tr}(\Psi Y^{-2})}{\partial Y} = \frac{1}{2} [Y^{-1} \Psi Y^{-2} + Y^{-2} \Psi Y^{-1}]^\top \quad (77)$$

we can calculate the mode by setting the derivative of the log-pdf to zero:

$$\frac{\partial \log \mathcal{IW}_{\text{sqrtm}}(Y, \Psi, \nu)}{\partial Y} = \frac{-(\nu+p) \det(Y) Y^{-\top}}{\det(Y)} + \frac{1}{2} [Y^{-1} \Psi Y^{-2} + Y^{-2} \Psi Y^{-1}]^\top \quad (78a)$$

$$= -(\nu+p) Y^{-\top} + \frac{1}{2} [Y^{-1} \Psi Y^{-2} + Y^{-2} \Psi Y^{-1}]^\top \quad (78b)$$

$$\Rightarrow (\nu+p) Y^{-1} = \frac{1}{2} [Y^{-1} \Psi Y^{-2} + Y^{-2} \Psi Y^{-1}] \quad (78c)$$

$$\Rightarrow 2(\nu+p) I_p = [Y^{-1} \Psi Y^{-1} + Y^{-2} \Psi] \quad (78d)$$

$$\Leftrightarrow Y = ? \quad (78e)$$

Using

$$\frac{\partial (X V X X)_{kl}}{\partial X_{ij}} = \frac{\partial}{\partial X_{ij}} \sum_{u_1, u_2, u_3} X_{k, u_1} V_{u_1, u_2} X_{u_2, u_3} X_{u_3, l} \quad (79)$$

$$= \delta_{i, k} \delta_{j, u_1} V_{u_1, u_2} X_{u_2, u_3} X_{u_3, l} \quad (80)$$

$$+ X_{k, u_1} V_{u_1, u_2} \delta_{i, u_2} \delta_{j, u_3} X_{u_3, l} \quad (81)$$

$$+ X_{k, u_1} V_{u_1, u_2} X_{u_2, u_3} \delta_{i, u_3} \delta_{j, l} \quad (82)$$

$$= I_{k, i} \cdot (V X X)_{j, l} + (X V)_{k, i} \cdot (X)_{j, l} + (X V X)_{k, i} \cdot I_{j, l} \quad (83)$$

$$\Rightarrow \frac{\partial X V X X}{\partial X} = I \otimes V X X + X V \otimes X + X V X \otimes I \quad (84)$$

$$\frac{\partial (X^{-1} V X^{-1} X^{-1})^\top}{\partial X} = -[I \boxtimes V X^{-1} X^{-1} + (X^{-1} V)^\top \boxtimes X^{-1} + (X^{-1} V X^{-1})^\top \boxtimes I]^T (X^{-1} \boxtimes X^{-\top}) \quad (85)$$

$$\frac{\partial (X^{-1} X^{-1} V X^{-1})^\top}{\partial X} = -[I \boxtimes X^{-1} V X^{-1} + X^{-\top} \boxtimes V X^{-1} + (X^{-1} X^{-1} V)^\top \boxtimes I]^T (X^{-1} \boxtimes X^{-\top}) \quad (86)$$

With these rules we can calculate the Hessian

$$\frac{\partial^2 \log \mathcal{W}_{\text{sqrtm}}(Y, \Psi, \nu)}{\partial^2 Y} = \frac{\partial}{\partial Y} - (\nu + p)Y^{-\top} + \frac{1}{2}[Y^{-1}\Psi Y^{-2} + Y^{-2}\Psi Y^{-1}]^\top \quad (87a)$$

$$\stackrel{\text{symmetry}}{=} \frac{\partial}{\partial Y} - (\nu + p)Y^{-1} + \frac{1}{2}[Y^{-1}\Psi Y^{-2} + Y^{-2}\Psi Y^{-1}]^\top \quad (87b)$$

$$= (\nu + p)(Y^{-1} \otimes Y^{-\top}) \quad (87c)$$

$$- \frac{1}{2}\{[I \boxtimes \Psi Y^{-1} Y^{-1} + (Y^{-1}\Psi)^\top \boxtimes Y^{-1} + (Y^{-1}\Psi Y^{-1})^\top \boxtimes I]^T (Y^{-1} \boxtimes Y^{-\top}) \quad (87d)$$

$$+ [I \boxtimes Y^{-1}\Psi Y^{-1} + Y^{-\top} \boxtimes \Psi Y^{-1} + (Y^{-1}Y^{-1}\Psi)^\top \boxtimes I]^T (Y^{-1} \boxtimes Y^{-\top})\} \quad (87e)$$

$$(87f)$$

However, since we don't know the solution to the mode this result is of limited value to us.

However, if we choose the the approximation

$$\frac{\partial \text{tr}(\Psi Y^{-2})}{\partial Y} = \frac{1}{2}[Y^{-1}\Psi Y^{-2} + Y^{-2}\Psi Y^{-1}]^\top \approx 2\Psi Y^{-3} \quad (88)$$

we can find explicit formulations of the mode and covariance matrix. The mode is

$$\frac{\partial \log \mathcal{W}'_{\text{sqrtm}}(Y, \Psi, \nu)}{\partial Y} = \frac{-(\nu + p) \det(Y) Y^{-\top}}{\det(Y)} + \frac{1}{2} 2\Psi Y^{-3} = -(\nu + p)Y^{-\top} + \Psi Y^{-3} \quad (89a)$$

$$\Rightarrow (\nu + p)Y^{-1} = \Psi Y^{-3} \quad (89b)$$

$$\Leftrightarrow (\nu + p)\Psi^{-1} = Y^{-2} \quad (89c)$$

$$\Leftrightarrow Y = \text{sqrtm}\left(\frac{1}{(\nu + p)}\Psi^{-1}\right) \quad (89d)$$

It also means we can compute the Hessian and insert the mode

$$\frac{\partial^2 \log \mathcal{W}_{\text{sqrtm}}(Y, \Psi, \nu)}{\partial^2 Y} = \frac{\partial}{\partial Y} - (\nu + p)Y^{-\top} + (\Psi Y^{-3})^\top \quad (90a)$$

$$= \frac{\partial}{\partial Y} - (\nu + p)Y^{-\top} + (Y^{-\top} Y^{-\top} Y^{-\top} \Psi^\top Y^{-3}) \quad (90b)$$

$$\stackrel{\text{symmetry}}{=} \frac{\partial}{\partial Y} - (\nu + p)Y^{-1} + Y^{-3}\Psi \quad (90c)$$

$$= (\nu + p)(X^{-1} \otimes X^{-1}) - [I_p \otimes X^{-2}\Psi + X^{-1} \otimes X^{-1}\Psi + X^{-2} \otimes V](X^{-1} \otimes X^{-1}) \quad (90d)$$

$$= (\nu + p)(X^{-1} \otimes X^{-1}) - [X^{-1} \otimes X^{-3}\Psi + X^{-2} \otimes X^{-2}V + X^{-3} \otimes V X^{-1}] \quad (90e)$$

$$\stackrel{\text{mode}}{\Rightarrow} (\nu + p)^2(\Psi^{-\frac{1}{2}} \otimes \Psi^{-\frac{1}{2}}) - (\nu + p)^2[\Psi^{-\frac{1}{2}} \otimes \Psi^{-\frac{1}{2}} + \Psi^{-1} \otimes I_p + \Psi^{-\frac{3}{2}} \otimes \Psi^{\frac{1}{2}}] \quad (90f)$$

$$= -(\nu + p)^2[\Psi^{-1} \otimes I_p + \Psi^{-\frac{3}{2}} \otimes \Psi^{\frac{1}{2}}] \quad (90g)$$

$$= -(\Psi^{-\frac{3}{2}} \otimes \Psi^{\frac{1}{2}})(\Psi^{\frac{1}{2}} \otimes \Psi^{\frac{1}{2}} + I_{p^2}) \quad (90h)$$

which could be inverted more easily using equation 5 of <http://papers.nips.cc/paper/4281-efficient-inference-in-matrix-variate-gaussian-models-with-iid-observation-noise.pdf>

12.3.2 The Bridge for the sqrtm-transformed inverse Wishart distribution

TODO

Some equations to explain what the hell is going on in our derivations

TODO

Notation:

x : variable of the probability distribution in standard basis

π : variable of the probability distribution in standard basis (if the space is a probability space)

y : variable of the probability distribution in transformed basis

u : helper variable for non-trivial transformations

$\phi(x)$: sufficient statistics

w : natural parameters

$Z(w)$: partition function/normalization constant

$h(x)$: base measure
